T. O'B. HUBBARD & J. H. LEDEBOER

FOREWORD

History is silent concerning the life and circumstances of Thomas Walker, portrait painter of Hull. His sole claims to immortality are the two editions of his pamphlet upon flying, which exhibit him as an earnest amateur with a hobby and some small conceit of himself. He fumbles with great truths : knows much, but fails to order his knowledge, and hovers on the brink of great achievements in a way that is quite exasperating. For these reasons his writings are, perhaps, the most fascinating of all those of the pioneers, and this fascination is deepened by the drawings that accompany them. In the following reprint both his editions are published together for the first time. The first edition has been reprinted several times, but never with the original illustrations, which are here given from both editions.

It will be seen that between 1810 and 1831 his knowledge increased to a considerable extent. The drawings in the second edition are infinitely more practicable, and his machine bears a remarkable likeness to Professor

Montgomery's glider turned upside down. However, as neither of the models shown in fig. 3 and fig. 6 could have ever performed in the manner he describes, one is almost led to the supposition that, with the natural instinct for secrecy and mystery that in varying degrees every inventor possesses, he has purposely concealed the essential point of his discoveries and has designed the illustrations to bewilder rather than to elucidate. This theory is not pressed, but it is patent that his remarks are pregnant with the suggestion of greater knowledge—whether instinctive rather than realised, it is immaterial to decide.

It is, in fact, the suggestiveness of his work that renders Thomas Walker valuable, that gives him his recognised niche in history and crowns him with the sacred halo of the pioneer. All the little side-lights and minutiae with which he entertains us are so sensible and so prophetic. He explains how steering can be effected by the shifting of the pilot's body, which, 80 years afterward, Lilienthal put to practical demonstration. The art of flying, he says, is as truly mechanical as the art of rowing a boat—a marvellous phrase for a century ago.

And if, in 1831, with the high courage of his convictions impaired by the burden of years, he allows himself momentarily to suggest that the insertion of gas between the upper and lower surfaces of the wings might render the result doubly sure, the lapse is immediately followed by a firm expression of opinion that this guarantee of success will not be necessary.

Though circumstances of birth and education caused him to be overshadowed by the florid genius of Cayley, the historian will see in the accident of Walker's writings a far greater earnest of the subsequent rise and apotheosis of the art of flying than in the more elaborate calculations of his brilliant contemporary.

N.B.—The square brackets in the following pages denote matter that appeared ONLY in the second edition.—Eds.

TREATISE

UPON THE

ART OF FLYING,

BY MECHANICAL MEANS,

WITH A

FULL EXPLANATION OF THE NATURAL PRINCIPLES
BY WHICH BIRDS ARE ENABLED TO FLY ;

LIKEWISE

*INSTRUCTIONS AND PLANS*FOR MAKING A FLYING CAR WITH WINGS, IN WHICH A MAN MAY
SIT, AND, BY WORKING A SMALL LEVER, CAUSE HIMSELF TO
ASCEND AND SOAR THROUGH THE AIR WITH THE
FACILITY OF A BIRD.

ILLUSTRATED WITH PLATES.

SECOND EDITION.

BRISTOL:

PRINTED BY WILLIAM HENRY SOMERTON, AT THE MERCURY-OFFICE,
AND MAY BE HAD OF THE AUTHOR.

1831.

DESCRIPTION OF THE PLATES.*

THE SECTION OF THE CAR.

No. 1. *a* The right wing.—*b* One of the side rails, upon which the wing must work with two joints to admit of a vertical motion, for no other motion can answer the purpose.—*c c* The two cross bars which hold the side rails together.—*d* Half of the tail.—*e* The back rib, fixed to the middle of the hinder cross bar, and then brought down to the bottom of the middle rib.—*f* The middle rib, fixed to the two side rails, and *bended* down three feet below, to form the bottom of the car.—*g* One of the fore ribs, fixed to the fore corner of the car on the right side, and then to the back rib at the bottom.—*h* The upright lever, fixed into the crank, to move the wings with.—*i* The axis for the crank to work upon, which must be placed two feet nine inches below the top edge of the car.—*j j* Two iron rods two feet nine inches long, to unite the inner ends of the wings to the ends of the crank head.—*k* Two oblique prongs to be fixed to the back rib, projecting forward, with the points twenty inches asunder, and fifteen inches below the crank when it stands in a level direction. They are to keep extended the fore part

* This description refers only to the plates which appeared in the first edition, viz., Figs. 1 to 5. Figs. 6 to 12 (facing p. 33) were published, without description, in the second edition.—EDS.

of the bottom of the car, so as to admit of room for the crank head to work up and down.—*l* The crank, two feet six inches long; this causes the wings to strike up and down, by means of the man working the lever backwards and forwards.—*m* The crank head, eighteen inches long.—*n* The seat for the man to sit upon, fixed to the back rib.—*o* A piece of wood projecting from the middle of the fore cross bar, to which is fixed a head made of cork-wood, and a number of small cords to be stretched to the two fore ribs, and the prongs at the bottom of the car; in the same manner cords are to be fixed all round the car, to support the silk which covers the outside.—*p p* Two joints which fasten the wings to the edge of the car.

PLAN OF THE CAR.

No. 2. 1 1 1 1 The shafts of the left wing.—2 2 The two side rails which form the top edges of the car, and upon which the wings are to be fixed with two joints each.—3 3 Two cross bars three feet each, holding the two side rails together.—4 The middle rib with its two ends fastened to the side rails, bending down in the middle, so as to form the bottom of the car three feet below the top rails.—5 5 The two fore ribs to be united to the fore ends of the side rails, and to bend down to the middle rib, at the bottom of the car, and there joined to the back rib, which must have its upper end well fixed to the hindermost cross bar.—6 The seat for the man to sit upon, fixed with its front ten inches behind the axis of the crank.—7 7 Two foot-boards for the man's feet to rest upon.—8 The crank, two feet six inches long.—9 The head of the crank, eighteen inches long.—10 The axis of

the crank, eighteen inches long.—11, 12 Two iron rods, fixed with joints to the two inner ends of the wings, and then to the two ends of the crank head.—13, 13 Two shafts to give expansion to the tail.—14 Small cords to brace the fore shaft of the wings.—15 Eight longitudinal parallel cords, well stretched, to which slips of silk must be sewed, each slip about seven inches broad; and the oblique cords, 16, must be well stretched and knotted to them at each part where they cross.—17 A number of small threads, running across the under side of the wings at about four inches asunder, to which each slip of silk must be attached, that they may be prevented from opening more than half an inch from each other when the wings move upwards.

No. 3. A pair of paper wings, ten inches each in length, with a tail ten inches long down the middle; the frame or skeleton of the wings and tail to be formed of small sticks, about the thickness of a crow quill, and the paper must be fixed on by its edges being neatly pasted to the sticks; at the posterior angle of the wings the *paper* must have a piece of fine thin cloth pasted upon it to give strength to it at the corner.

No. 4. Represents a pigeon flying from the ground in the angle of sixty.

No. 5. Represents a grebe flying horizontally.

TO THE

Right Hon. Earl STANHOPE.

MY LORD,

AS far as an obscure individual like myself can judge of exalted characters, I am induced, in unison with public opinion, to hold a belief that your lordship is possessed, in a very superior degree, both of genius and a knowledge of the sciences, as well as a known predilection for everything that is calculated to improve and extend the mechanic arts, or to meliorate the condition of mankind. To acknowledge also that your lordship is equally preëminent in the senate is but paying a tribute which is *very justly due* to your patriotism, and the great exertions which you have made in advocating the cause of humanity. Every *friend* to his country must hold in grateful remembrance the energetic and manly opposition which your lordship evinced to prevent the commencement of a war more undefined in its object, more inefficient, and more direful and ruinous in its consequences to our country than any war it was ever madly and unjustly plunged into. My countrymen have *now* great cause also to remember, with indignation and deep regret, that, in return for your opposition to the origin of those baneful effects, which your lordship clearly foretold, and are now but too severely felt; in return for your wise counsels and patriotic zeal, your lordship met with every

coarse insult and contumely which blind folly and malice could suggest. But your lordship has this inestimable consolation that your life has been most *honourably* engaged not with the savage arts of murder, not with the burning of towns and the destruction of their inoffending and defenceless inhabitants; not with the filling of Europe with miserable widows and orphans; not with the ruin of manufactures and commerce, and the violation of the sacred constitutional rights and liberties of your countrymen; not with the low, base, and contemptible arts of any corrupt and venal faction; not with the arts of tyranny and oppression, or force and fraud; not with the machiavelian arts; but with the *noble arts* which are conducive to *peace, civilization, and the convenience and happiness of mankind.*

Had I invented a diabolical engine that would effectually have swept off from the earth a considerable portion of its *unwary* inhabitants, I should never have thought of addressing your lordship; I must have sought patronage from another quarter; but, considering the subject of this work, I thought no one was more able than your lordship to form a just estimation of its merits. I have, therefore, taken the liberty of dedicating it to you, flattering myself that the theory it contains will be honoured with your lordship's approbation which will greatly contribute to the pleasure of,

My Lord,

Your Lordship's humble Servant,

THOMAS WALKER.¹⁷⁸

PREFACE.

I AM laying before the public a treatise upon a subject perhaps as extraordinary in its nature as anything that has lately come before them. [Since I first published my "Thoughts upon the Art of Navigating the Air," I have greatly improved my plan for accomplishing that desirable attainment; and, as the first edition is now out of print, I am induced to offer a second edition to the public, wherein I shall show how to produce a sustaining power upon the air, in a *two-fold* degree to what I had before discovered; also a plan for *perfect* steerage, with a very *superior* method for launching the machine upon the air;] and after a candid perusal, should it meet with approbation from the friends to arts and sciences, my utmost pride will be gratified. The flight of birds, although so common and familiar to our sight, is certainly as great a phenomenon as any in the creation; and artificial flying, when accomplished, may be considered as one of the greatest wonders of the mechanic arts, which I firmly believe attainable upon the plan I have suggested.

In this little work I have shown that birds' wings do not increase their expansion in exact ratio with the increased specific gravity of their bodies; I have given a demonstration of the cause of the projectile motion of birds, the discovery of a true knowledge of which has bid

defiance to philosophers in all ages, which, with other discoveries, I trust will prove that I have given consistency to what henceforth may be denominated the *science* of flying, and which may alone be deemed of considerable importance to science, had nothing more than that been brought forward; but as I have gone much further, and have advanced arguments, and given plans to render the *art of flying practicable*, the importance of this little treatise becomes obvious, more particularly so if we take into consideration the various purposes to which artificial flying may be applied.

When my work was just ready for the press, I was much surprised at the account a friend gave me of what he had seen that day upon flying, in a monthly journal. I immediately procured a sight of it, and found it to be an ingenious paper written by Sir George Cayley, and I own I was astonished at the perusal. I conceived it to be very extraordinary that two persons, not having the least knowledge of each other, should be publishing their thoughts at the same time upon such a subject; nor was I less surprised to find the subject treated of there in a manner so rational and far superior to anything I have ever seen before. From what Sir George has thought, and the calculations he has made upon the subject, he is so sanguine in his belief that flying will be effected as to say, in one part of his paper, as follows: "I feel perfectly confident, however, that this noble art will soon be brought home to man's general convenience, and that we shall be able to transport ourselves and families, and their goods and chattels, more securely by air than by water, and with a velocity of from 20 to 100 miles per hour."—*Vide* Nicholson's Journal for November, 1809.

For my own part, whatever reason I may have to be sanguine of success, I have made a resolution to suppress in my work every thought that confidence could suggest beyond what I could give demonstration of, along with the clearest directions how to attain the end in view ; thereby putting it out of the power of critics to say that the principles of my theory have not a good foundation.

Notwithstanding, from the novelty and singularity of the subject, I do expect to meet with a good deal of raillery and sarcasm. The wits will tell me that I am flighty, and the more serious and heavy part of mankind, who are too ponderous for such aerial flights, will express a disapprobation of my scheme ; but I do not write for such folks, my sole aim is to deliver my thoughts to the public, in hopes that *men of genius and science* may turn their attention to a subject that may not before now have attracted their notice, that, by their aid and assistance, the art may be brought into practice ; and, as this country stands unrivalled in arts, I hope we shall not be long without a Society for the encouragement of the art of flying. Columbus was laughed at when he talked of a continent beyond the Atlantic ; but flighty as he might appear he found it, and *wise* men lost it !

[Since I published the first edition of this treatise, copies have been taken into Holland, Germany, France, America, and other countries ; and in the *Literary Gazette*, of Sept. 11, 1830, there is a report of there being a Mr. Genet, in America, and three rivals in France, all busily employed in making machines for travelling in the air, and all are equally sanguine of success.]

A TREATISE, &c.

WE learn, from several authors, that, in different ages of the world, the art of flying has been attempted by various means, all of which have hitherto failed of success. When we take into consideration the different methods which are recorded to have been tried, we cannot be surprised that they have all failed, since, compared with what is contained in the following pages, they will obviously appear to be nothing more than mere whims and contrivances, all utterly destitute of the true nature and science of flying.

I am conscious that many of my readers, who have never been led to notice the remarks that many eminently learned men have made upon this art, will be tempted at the first sight of my title page to ridicule a treatise upon artificial flying; for there is not a more common saying, when a person has taken some great difficulty in hand, than that such a thing is as impossible to be done *as for one to fly in the air*. I do assure all such that my treatise is not founded upon a whim of the moment, but from mature deliberation on the display of nature. The study of the works of nature has been to me, during the greatest part of my life, a source of amusement and inexpressible delight. The natural history of birds has particularly occupied my attention, and that enviable faculty which

they possess of flying has greatly excited my curiosity, and led me to that study by which I have obtained a *true knowledge* of the mechanical principles by which they fly, a knowledge which I do not hesitate to declare has hitherto remained undiscovered, although it has been the object of the study and contemplation of many of the most eminent philosophers of past ages.

That great observer of the works of nature, Solomon, did not overlook the subject of flying, but speaks of it in his book of *Proverbs*, xxx, 18, 19—"There be three things which are too wonderful for me, yea four, which I know not: *the way of an eagle in the air*, the way of a serpent upon a rock." I beg also to remind such of my readers as doubt the possibility of flying that many useful and valuable mechanical inventions, which are now complete and become common, would, a century or two past, have been treated as visionary or impracticable; or had they been accomplished at such periods their effects would have been attributed to witchcraft. I have not the least doubt of being successful in the art of flying, if I had it in my power to give it a fair trial. My invention for attaining the art is founded *entirely upon the principles of nature*; and although these principles are as old as the creation, they have never, until now, been properly attended to. How much are we indebted to the study of nature for discoveries of the greatest importance? and from this delightful study many more are yet to be expected.

The love of pleasure is natural to man, and to gratify this propensity he eagerly attends to every artificial entertainment that is offered to him. He resorts to theatres and operas, to Newmarket, and other haunts of vanity and folly, as if pleasure were nowhere else to be found;

at the same time what an inexhaustible fund of entertainment is overlooked by all but a few, although constantly displayed in the wonderful exhibition of the works of nature.

What a pity it is that minds of men are not more generally and forcibly struck with the pure and tranquil delights resulting from the universal study of nature. What riot, confusion, waste of time, loss of money and of health, might be avoided if this pleasing and truly-enlightening study could be made fashionable. What an infinite stock of ideas it would create; how much it would enrich the human mind, and afford matter for social conversation and entertainment far superior to the unimportant subjects which too generally occupy the minds and tongues of men.

I will now present my readers with some account of various schemes which have been tried to accomplish the art of flying, and shall show the cause of their insufficiency. I shall explain the natural mechanical means by which birds are enabled to fly, and my readers will then be able to judge how far my invention for flying corresponds with the natural science, and is thereby calculated to succeed. I shall show likewise the comparative difference between the specific gravity of the humming bird and the condor, also the different expansion of the wings. I shall compare the weight of a man with the weight of the condor, and thereby determine the necessary dimensions of a pair of wings which would enable a man to fly; and, lastly, I will explain an experiment which I have made in order to demonstrate the principles of artificial flying, and give directions for making a machine wherein a man may sit, and, by working a pair

of wings with a lever, be able to ascend into the air, and fly with as much safety and ease as a bird.

During the early part of my life I have dissected a great many birds, and since studied very minutely the mechanism of their wings, tails, and all the parts which they employ in flying.

I have long been accustomed to contemplate a bird as a living machine, formed by the Almighty Creator, either to run upon the earth, to dive in the waters, or to ascend into or fly through the air; and when I examine its various parts, and find such an exquisite display of wisdom in each being formed so perfectly to answer the use it is applied to; when I see the effect of the whole, that such a wonderfully organized animated piece of matter can quit the earth and soar aloft in the air, it appears to me a miracle, and I am struck with admiration.

It is now almost twenty years since I was first led to think, by the study of birds and their means of flying, that if an artificial machine were formed with wings, in exact imitation of the mechanism of one of those beautiful living machines, and applied in the very same way upon the air, there could be no doubt of its being made to fly; for it is an axiom in philosophy that the same cause will ever produce the same effect.

It is easy to demonstrate that a bird is no more able to fly than a man without the mechanical effect of wings;¹

¹ The ostrich, in the torrid regions of Africa; the emu, in the extensive plains of Paraguay, in South America, which, standing erect, is about seven feet high, its legs are three feet long, its thighs are nearly as thick as the thighs of a man, it runs so swift that the fleetest dogs are foiled by it; the cassowary and the dodo, in the Molucca Islands; and the penguins, in the Straits of Magellan and the South Sea Islands. All these birds are as utterly incapable of flying as a man, none of them being provided with wings for that purpose.—T.W.

therefore, when a man is furnished [with a car to sit in and] with a pair of wings large enough, and can apply them in the same manner as a bird does, and with sufficient power, there can be no reason to doubt of a man being able to fly as well as a bird. The machine which I have planned is as close a copy of the natural mechanism of a bird as artificial means will admit of; and when my readers are made thoroughly acquainted with both the natural and artificial means of flying, I flatter myself they will then be willing to acknowledge that my scheme is a very rational one, highly calculated to insure success in the accomplishment of the art of flying, one of the most extraordinary and desirable arts with which we can be acquainted.

Although I have, for many years, been extremely anxious to bring the machine into effect, and am very sanguine in my expectations of success (for I positively assert that flying cannot be accomplished on any other plan than the one I propose), I, unfortunately, have ever found myself unable, from my professional avocations and other circumstances, to put it in practice, or I should long since have made the experiment.

Finding, therefore, that to no purpose I have deferred, for a long time, its execution, which I deeply regret, and the prospect of the future being not more favourable, I am induced to publish my plan, in the hope that the lovers of the arts and sciences, when I have laid before them a scheme so practicable, will readily be induced, for the honour of science and our country, to contribute to the means of bringing it into practice, and demonstrate to their fellow mortals how they may gain a perfect dominion over another element.

In almost every nation where arts and sciences have flourished, persons have manifested a wish to discover the art of flying. In Rome and in Paris particularly different persons, and in ages remote from each other, have tried experiments with wings formed of various materials, which have been fastened to their arms, but none of them succeeded, there not being strength sufficient in a man's arms to enable him to fly with detached wings fastened to him, leaving the whole weight of his body unsupported.

Friar Bacon, who lived nearly five centuries ago, wrote upon the subject, and he affirms that the art of flying is possible; and many others have been of opinion that, by means of artificial wings affixed to the arms or legs, a man might fly as well as a bird.

The philosophers of the reign of King Charles the Second were much engaged with this art. The famous Bishop Wilkins, who, in 1672,* published a treatise upon flying, was so confident of its practicability, that he says he does not question but that in future ages it will become as common to hear a man call for wings when going a journey as it is now to call for his boots and spurs.

In the year 1709, as we gather from a letter published in France in 1784, a Portuguese, Friar de Gusman, applied to the king to encourage him in the invention of a flying machine. The principle upon which it was constructed, if indeed it had any principle, seems to have been that of a paper kite. The machine was in a form of

* This is hardly correct. The 1st edition of "Mathematical Magic," of which the 2nd part entitled "Dædalus or Mechanical Motions" contained several chapters on the subject, appeared in 1648.—EDS.

a bird, and contained several tubes through which the wind was to pass in order to fill a certain sail, which was to elevate it; and when the wind was deficient the same was to be effected by means of bellows concealed within the body of the machine. The ascent was also to be promoted by the *electric* attraction of pieces of amber placed in the top, and by two *spheres* inclosing *magnets* in the same situation.

Thesesilly inventions show the very low state of science at that time in Portuga^l, especially as the king, in order to encourage him in his further experiments in such an useful invention, granted him the first vacant place in his College of Barcelos or Santerim, with the first professorship in the University of Coimbra, and an annual pension of 600,000 reis during his life. Of this De Gusman it is also related that, in the year 1736, he made a wicker basket of about seven or eight feet diameter, and covered it with paper, which raised itself about 200 feet in the air, and the effect was generally attributed to witchcraft.

Mr. Willoughby, after observing that the pectoral muscles of a man, in proportion to his weight, are many degrees too weak for flying, recommends to him who would attempt the art with the desire of success to contrive and adapt his wings in such a manner that he may work them with his legs and not with his arms, because the muscles of the legs are much stronger.

The celebrated Lord Bacon wrote on the subject of flying, and believed it practicable, but it seems he could no more direct how it was to be done than any other who had written before him on the same subject.

Thus much, for the satisfaction of my readers, I have thought proper to make mention of what has been attempted in the accomplishment of this wonderful art; but were I to adduce all that has been said and done, at different periods of time, I could compile a large volume of that alone, which would answer no other end than that of curiosity, and to show that no one has ever understood the natural means of flying, which is the only knowledge that can guide us to the completion of artificial flying, and which I hope and trust will be clearly demonstrated in this treatise.

As I shall have occasion to refer to various birds, possessing different powers of flight, in illustration of my design, I here introduce the history of the condor, for the information of such of my readers as may not be acquainted with it.

The condor is a native of America, and hitherto naturalists have been divided whether to refer it to the species of the eagle or to that of the vulture. Its great strength and activity seem to give it a claim to rank among the former, whilst the baldness of its head and neck is thought to degrade it to a rank amongst the latter. It is, however, fully sufficient for our plan to describe its manners, form, weight, expansion, and power; we will therefore leave to nomenclators to decide upon its class. If size (for it is by much the largest bird that flies) and strength, combined with rapidity of flight and rapacity, deserve preëminence, then no bird can be put in competition with it; for the condor possesses, in a higher degree than the eagle, all the qualities that render it formidable not only to the feathered tribe, but to beasts, and even to man himself.

Acosta, Garcilasso, and Desmarchais assert that it measures 18 feet across the wings when expanded; its beak is so strong as to pierce the body of a cow; and it is positively asserted that two of them are capable of devouring that animal. They do not even abstain from attacking man himself; but, fortunately, there are but few of the species. *The Indians say that they will carry off a deer or a young calf in their talons as an eagle would a hare or rabbit, that their sight is piercing, and their manners terrific.* According to modern authors they only come down to the sea coast at certain seasons, particularly when it is supposed their prey fails them upon the land; that they then feed upon dead fish and such other nutritious substances as the sea throws upon the shore.

Condamine says he has frequently seen them in several parts of the mountains of Quito, and has observed them hovering over a flock of sheep; and he thinks they would, at one particular time, have attempted to carry some of them off had they not been scared away by the shepherds. Labat says that this bird has been described to him, by those who have seen it, as having a body as large as a sheep, and that its flesh is as tough and disagreeable as carrion. The Spaniards residing in that country dread its depredations, there having been *many instances of its carrying off children.* Mr. Strong, the master of a ship, relates that, as he was sailing along the coast of Chili, in the thirty-third degree of South latitude, he observed a bird sitting upon a high cliff near the shore, which one of the ship's company shot with a leaden bullet and killed. They were greatly surprised when they beheld its magnitude, for when the wings were extended they measured 13 feet from one tip to the other; one of

the quill feathers was 2 ft. $4\frac{3}{4}$ in. in length, and $1\frac{1}{2}$ in. in circumference.

Mons. Feuilleé, whose description alone is accurate, has given a still more circumstantial account of this amazing bird.

“In a valley of Illo, in Peru,” says he, “I discovered a condor perched on a high rock before me. I approached within gun-shot and fired, but as my piece was only charged with swan-shot the lead was not heavy enough to bring the bird down. I perceived, however, by its manner of flying, that it was wounded, and it was with a good deal of difficulty that it flew to another rock about 500 yards distant on the seashore. I therefore charged again with the ball and hit the bird under the throat, which made it mine. I accordingly ran up to seize it; but even in death it was terrible, and defended itself upon its back with its claws extended against me, so that I scarcely knew how to lay hold of it. Had it not been mortally wounded I should have found it no easy matter to take it, but I at last dragged it down from the rock, and, with the assistance of one of the seamen, I carried it to my tent to make a coloured drawing of it. The wings of this bird, which I measured *very exactly*, were 12 ft. 3 in. (English) from tip to tip. The great feathers, which were of a beautiful shining black, were 2 ft. 4 in. long. The thickness of the beak was proportionable to the rest of the body, the length about 4 in., the point hooked downwards and white at its extremity, and the other part was of a black jet. The thigh bones were 10 in. long, the legs 5 in., the toes and claws were in proportion, and the legs were covered with black scales. The little nourishment which these birds find on

the coast, except when a tempest throws up some great fish, obliges the condor to continue there but a short time. They usually come to the coast at the approach of evening, stay there all night, and fly back in the morning."

I now proceed to describe the construction and application of the wings of a bird. How properly are they formed to fulfil the uses they were made for: The first is to expand, and by that means to give the bird a secure hold upon the air below it, which hold is always in proportion to the dimensions of the wings. The tail produces the same effect. We see that by means of a pair of wings and a tail duly expanded, in a perfectly *passive state* and aloft in the air, without any muscular motion, a bird procures a suspending power, which counteracts the specific gravity of its body, and prevents it being precipitated to the ground; such is the effect of the wings and tail when in a *passive state*.

I will next take some notice of the quill feathers, which are replete with proofs of the wisdom of the Almighty artist who made them. As they were intended to swim within so light and subtle a fluid as the air is, it was necessary that they should be formed of the lightest materials imaginable; and as they were intended to strike upon the air with great power and rapidity, it was requisite that they should possess in the shafts great strength with elasticity; it was expedient too that the quill feathers should separate and open to let the upper air pass through the wings, to facilitate their ascent when they are struck upwards; it was also necessary that they should all shut close together, forming each wing into a complete surface or web, when they are, by the muscular power of

the bird, forced down in order to give a more secure hold upon the air below, and by that means keep the bird up.

Now if we do but examine the quill feathers we shall find in the shafts astonishing strength with elasticity, and very little specific gravity indeed. The webs of the quill feathers are broader on one side of the shaft than the other, which causes them to open as the wings move up and to shut as they come down, exactly answering the purposes I have already mentioned; therefore, we see how wonderfully-complete the wings are in all their parts, and how effectually they serve all the uses required.

I will now show the application and effect of the wings and tail in *an active state*. When a bird, by the power of its pectoral and deltoid muscles, puts its wings into action and strikes them downwards in a perfectly vertical direction upon the air below, that air being compressed by the stroke of the wings makes a resistance, by its elastic power, against the under side of the wings, in proportion to the rapidity of the stroke and the dimensions of the wings, and forces the bird upwards; at the same time the back edges of the wing being more weak or elastic than the fore-edges, they give way to the resisting power of the compressed air, which rushes upwards *past the same back edges*, acting against them with its elastic power, and thereby *causes a projectile force*, which impels the bird forwards; thus we see that by one act of the wings the bird produces both *buoyancy* and *progression*. When the tail is forced upwards, and the wings are in action, the bird ascends, and forced downwards it consequently descends; but the most *important use of the tail is to support the posterior weight of the bird*, and to prevent the vacillation of the whole.

Thus having discovered and explained to my readers the natural mechanical means by which birds accomplish flying, they will be able to see that the plan upon which I have formed my scheme for artificial flying is perfectly analogous to the principles of nature, which certainly ought to be clearly understood, and taken as our only guide, before we can ever expect to arrive at success in the art of flying ; but with the knowledge of these principles *there cannot remain a doubt of success.*

When we first think of a man attempting to fly by mechanical means, we are induced, considering his specific gravity, to pronounce it impossible ; and had we never seen or known of any bird larger than a humming bird, whose weight does not exceed one drachm, and whose diminutive wings measure only three inches from tip to tip ; and were to be told by some traveller that he had seen a bird with a body as large as a sheep, that had wings of twelve feet expansion, and that it could quit the earth and ascend into the air with its ponderous body, and there fly about with as much ease as the little humming bird, we should think it too marvellous a tale to be credited. But as we are accustomed to see, almost every day, birds of such various dimensions and specific gravity as are exhibited by nature, from the humming birds to the common wren ; from the wren, through a numerous gradation, up to the eagle, we can readily give credit to the history of the wonderful condor in South America, whose existence is so well attested that we can have no reason to doubt of it, more especially as we witness so vast a gradation in the indigenous birds of our own country. I believe that there were two of these prodigious birds in the Leverian Museum [and I have seen one exhibited in a caravan of wild beasts.]

The following observations upon the wonderful difference in the weight of some birds, with their apparent means of supporting it in their flight, may tend to remove some prejudices against my plan from the minds of some of my readers. The weight of the humming bird is one drachm, that of the condor not less than four stone. Now, if we reduce four stone into drachms, we shall find the condor is 14,336 times as heavy as the humming bird. What an amazing disproportion of weight ! Yet by the same mechanical use of its wings, the condor can overcome the specific gravity of its body with as much ease as the little humming bird. But this is not all. We are informed that this enormous bird possesses a power in its wings, so far exceeding what is necessary for its own conveyance through the air, that it can take up and fly away with a whole sheep in its talons, with as much ease as an eagle would carry off, in the same manner, a hare or a rabbit. This we may readily give credit to, from the known fact of our little kestrel and the sparrow hawk frequently flying off with a partridge, which is nearly three times the weight of these rapacious little birds.

Let us attend to this subject a little further. Let us consider these wings of the condor, which, with a *mechanical action alone*, produce a power that is capable of carrying through the air both the bird and the sheep, weighing together not less than ten stone, which would then be 204,000 *times the weight of the humming bird !* When this is duly considered, with reference to my plan, what encouragement does it not give to prosecute the art of flying ? particularly so when we consider that a man of ten stone weight, in a machine weighing two stone, will only exceed the weight of the condor *one-fifth*

part; this is a mere trifle compared with the astonishing difference there is between the humming bird and the condor.

The condor carries ten stone, with wings of twelve feet expansion from tip to tip; the humming bird carries one drachm, with three inches expansion; the common wren is three times as heavy as the humming bird, and has but one inch more of wing; a pigeon weighs 16 ounces, which is 256 times as heavy as a wren, and has only ten times more expansion of wing; the goatsucker is forty times as heavy, and has seven times the length of wing. I could here carry the same observations upon other birds to a very great extent, but the above are instances sufficient to prove that birds' wings are not multiplied in their length in the same proportion with the increased weight of their bodies; therefore, as a man weighing ten stone and his machine two, as I have already shown, will only exceed in weight *one-fifth part* of the weight of the condor and his prey; and as the wings of the condor are about twelve feet, suppose we make a pair of wings of silk one-fifth longer than they are, which will be about fourteen feet and a half, I am thoroughly persuaded they will be found amply sufficient, as they will far exceed the progressive increase of birds' wings.

By attending to the progressive increase of the weight of birds, from the delicate little humming bird up to the huge condor, we clearly discover that the addition of a few ounces, pounds, or stones, is no obstacle to the art of flying; the specific weight of birds *avails nothing*, for by their *possessing wings large enough, and sufficient power to work them*, they can accomplish the means of flying equally well upon all the various scales and dimensions which we see in nature.

Such being *a fact*, in the name of reason and philosophy why shall not a man with a pair of artificial wings, *large enough* and with *sufficient power to strike them upon the air*, be able to produce the same effect.

I shall, after a few observations, proceed to describe how a machine may be made with a pair of wings, and a lever to work them with, so that any person will be able to see how far it is calculated to answer the purpose for which it is intended. This machine may be considered as a large artificial bird, and the man placed in the inside as the vital or moving power. All the attempts hitherto made in the art of flying, by different persons, according to historians, have been mere childish whims, not in the least degree calculated to insure success. They each made a pair of detached wings, some of silk, some of leather, and some of sheet iron and various other materials; they fastened them upon their shoulders or arms; thus equipped, they placed themselves upon some eminence, such as a high tower or a church steeple, then took to their wings; but few of them were fortunate enough to escape without some injury.

It is utterly impossible for a man to fly with a pair of wings fixed to his shoulders or arms, with the whole weight of his body hanging down and depending entirely on his pectoral muscles for support. These muscles in a man are many degrees too weak to keep extended a pair of wings of sufficient expansion to effectually counteract the specific gravity of his body. Let a man suspend the weight of his body, with his arms extended, holding to an horizontal beam by his hands, and he will very soon find the insufficiency of the strength of his arm to support his weight. On the plan which I have conceived for flying

the want of strength in the arms is amply provided for. By furnishing a man with a car to sit in [with two passive surfaces fixed to it of sufficient extent], the whole weight of his body is supported by it, and as he sits much in the same manner as if he were rowing a boat, he is enabled to bring into action his *whole bodily strength*, which *far exceeds* the strength of his arms only, and by sitting in such a position his strength can be exerted [applied to the active wings] with a far greater force than in any other attitude whatever; he at the same time gains an *additional advantage*, in this plan of mine, by exerting his strength upon a lever.

The two greatest requisites for accomplishing the art of flying are these—first, *expansion of wings large enough* to resist, in a sufficient degree, the specific gravity of whatever is attached to them;* second, *strength enough* to strike the wings with a sufficient force to complete the buoyancy, and give a projectile motion to the machine. With these two requisites combined *flying must be accomplished*; and upon my plan there can be no doubt of wings [passive surfaces] being made as large as ever they may be wanted; neither ought we to doubt of a man's ability, exerting himself in the way I have described, to bring into action as great a degree of strength, in proportion to his weight, as the condor is possessed of. Therefore, if we are secure of these two requisites, and I am very confident we are, we may calculate upon the success of flying with as much certainty as upon our walking [or navigating the ocean].

* In the second edition this sentence became: "first, *expansion of flat passive surfaces large enough* to reduce the force of gravity so as to FLOAT the machine upon the air with the man in it."—EDS.

When I first thought of artificial flying [*and discovered that the projectile force of birds is caused by having their wings formed with great strength along the front edges, and with the back edges very weak and elastic*], it occurred to me that it would be of some importance to try what effect a pair of [artificial] wings [made upon the same principles] would have upon the air, [expanded in a passive state] without any mechanical power to work them; I thought that if I were to suspend a weight from beneath them, they would prevent that weight from falling in a perpendicular line to the ground, [and at the same time dart forwards] and thereby demonstrate that the ideas I had conceived of the cause of the projectile motion of birds were well founded.

I therefore made the following experiment, to which I call the *particular attention of my readers*, as it *positively demonstrates the cause of the projectile motion*. I made a pair of small wings, of fine paper, and very small slips of wood to keep them extended, and fixed on a tail of the same materials, imitating, as near as I could, the wings and tail of a bird when expanded in a *passive state** (*vide fig. 3*). I then suspended a small weight from under them, with a piece of thread, exactly in the centre of gravity; I held them up as high as I could reach, then took away my hand, and left them flat upon the air, without giving any impulse to them whatever; and by the weight pressing downwards the air under the wings became, in some degree, compressed, and by its reaction against the under side and the *back edges* of the wings,

* In the second edition this sentence became: "I made a pair of small wings, of fine paper, and very small slips of wood extended along the front edges, with the back edges consisting only of paper, imitating, as near as I could," etc. (*vide fig. 6*).—EDS.

they were [sustained upon the air and] projected with an oblique descent from one end of the room to the other, carrying the weight all that distance, which, without the wings being of this particular construction, could not have been done.

Nº5

I had cause sufficient to exult in the success of my experiment which proved to me, in a very satisfactory manner, that what I had conceived to be the cause of the projectile motion of birds *was really the cause*, and that if I could but give a vertical motion to [a pair of] wings, so that they might strike upon the air with a sufficient force, they would then increase the reaction of the air [against the back edges], and instead of being projected in an oblique descent, totally overcome their specific gravity, and *continue flying in an horizontal direction.*

This is an experiment which any of my readers may make trial of for their own satisfaction and amusement [and that they may be better able to comprehend

me, I have given a representation of it in the plate annexed.] *

Another experiment, serving to show the different effect of buoyancy obtained by a parachute and by my paper wings, may be tried in the following manner:—Take two straight sticks, neatly dressed, about the thickness of a crow-quill and each about sixteen inches long, lay them across each other in the middle, at right angles, and tie them fast with a piece of thread; then tie a piece of thread from the ends of one stick to the other, so as to secure them at right angles; then take a sheet of gauze paper, and fasten all the four corners of it to the four ends of the sticks; but previous to this, paste upon the four corners of the paper four small slips of thin cloth in order to give sufficient strength; then suspend any small weight by a thread from the centre; let the whole fall from a height, and you will see the effect of a parachute in miniature; but this effect is very different from that of the paper wings; the parachute *sinks gradually down in a perpendicular line*, while the wings *dart forwards* to the distance of several yards.†

I have met with persons who have boldly asserted that it is impossible for a man to exert sufficient strength to raise himself up into the air by mechanical means alone; but the rashness and fallacy of such an assertion is com-

* Vide Fig. 6.

† In the second edition the following directions are given: "Take two straight sticks, neatly dressed, square, but tapering smaller from the middle to the ends, about three-eighths of an inch in thickness and each about sixteen or eighteen inches long, lay them across each other in the middle at right angles, and tie them fast with a piece of thread; then take a sheet of gauze paper, brush the sticks over with paste or gum, then stretch the paper well, and lay the sticks with the pasted side upon the paper; when it is dried upon the wood, suspend any small weight by four threads from the four ends of the sticks; let the whole fall," etc.
—EDS.

pletely refuted and exposed by M. Degen, in Vienna, who has very lately actually ascended *into the air*, to a considerable height, by sitting in a machine and giving action to two parachutes; and had he properly understood the principles of birds' wings, and considered the astonishing power in the reaction of the air, which may be *increased in proportion to any force exerted upon it, ad infinitum*, and possessed a complete knowledge of the principles upon which it enables birds to fly, he would have chosen wings and not parachutes, and might then have accomplished flying in perfection.¹

There is no doubt that, by large parachutes, worked by a mechanical power, a man may raise himself from the ground to a considerable height; but that cannot be properly called flying, because as the compressed air rushes from underneath the parachutes, to regain its equilibrium *on all sides alike*, there can be no *projectile motion* effected, without which *there can be no command or steerage*; [as that can *only* be obtained by going *through* the air without which] the whole apparatus will be driven whichever way the wind impels it; I therefore cannot give credit to that part of the account of M. Degen's performance which asserts that he flew *in various directions*, although I can readily believe in his having raised himself into the air, and think that great praise is due to him. I do not believe it possible, upon his plan, that he could have gone

¹ M. Degen, a watchmaker of Vienna, has invented a machine by which a person may raise himself into the air. It is formed of two parachutes, of taffeta, which may be folded up or extended at pleasure, and the person who moves them is placed in the centre. M. Degen has made several public experiments, and rose to the height of fifty-four feet, flying, in various directions, with the celerity of a bird. A subscription has been opened at Vienna to enable the inventor to prosecute his discoveries.—*Vide* the Monthly Magazine for September, 1809.—T.W. (M. Degen obtained this result by fastening his wings to a small balloon which the Magazine reprehensibly omits to mention.—EDS.)

in any other direction than *with* the wind ; but with a pair of wings constructed and worked according to the natural principles of flying, a projectile motion is obtained in as perfect a manner as buoyancy, *both of which* must be accomplished before we can have the benefit and pleasure of flying with *steerage*, and that upon the following plan only, viz. :—

Make a car of as light materials as possible, but with sufficient strength to support a man in it ; provide a pair of wings of about eight feet each in length, let them be horizontally expanded, and fastened upon the top edge on each side of the car, with two joints each, so as to admit of a vertical motion to the wings, which motion may be effected by a man sitting and working an upright lever in the middle of the car ; a tail of about seven or eight feet long, and the same breadth at its extremity, must be fixed to the hinder part of the car, and spread out flat to the horizon in the same manner as we see the tails of birds.*

The grebes, by their manner of flying, evince that the most important use of a bird's tail is *to support* the *posterior weight* of the body ; for the Creator having left the whole of this class of birds, of which we have five different

* In the second edition the following directions were substituted :
 “ Make a car of as light materials as possible, but with sufficient strength to support a man in it ; provide a pair of wings, of about four feet each in length ; let them be horizontally expanded, and fastened upon the top edge on each side of the car, with two joints each, so as to admit of a *vertical* motion to the wings, which motion may be effected by a man sitting and working an upright lever in the middle of the car. Extend in front of the car a flat surface of silk, which must be stretched out and kept fixed in a passive state ; there must be the same fixed behind the car ; those two surfaces must be both *perfectly equal* in length and breadth, and large enough to cover a sufficient quantity of air to support the whole weight as nearly in equilibrium as possible ; thus we shall have a great sustaining power in those passive surfaces, and the active wings will propel the car forward.”—EDS.

species indigenous in this country, all totally destitute of any portion of a tail, they are, consequently, always seen when flying to have their bodies hanging down nearly in a perpendicular direction, and appear to fly with great difficulty ; but this impediment in flying is of little consequence to them, their organization being perfectly adapted to their mode of living. They find their subsistence in lakes and pools, wherein they are incessantly diving, and, of course, are not obliged to fly until those places are

frozen up, when they are compelled to flutter off, as well as they are able, in search of some spring or swamp which is not affected by frost, where they find a temporary subsistence until their favourite lakes are relieved from a surface of ice ; they then return to their former haunts, when they again seem quite in their element. Here we find a class of birds, owing to their want of tails, possessing the power of flight in a very imperfect degree, compared with some birds. It also may be observed that birds having extraordinary large tails, as the magpie for instance, do not fly in the best manner ; none of these birds possess what seems to constitute the excellence of flying, viz., soaring and reposing upon the air ; this can only be effected when the weight of the body is upon an equipoise in the centre of the wings and tail, each bearing up its due proportion, and the expansion altogether so

large, as to bring the whole weight nearly in equilibrium with the atmosphere. This must be properly attended to in the construction of a flying machine.

To give a further security to the power of suspension, a sail of an equilateral triangle may be spread horizontally over the man's head, supported by a small light mast or bowsprit, at the height of three or four feet above the car; the sail must be expanded and fixed to the mast by a very light yard, presenting the base of the sail to the head of the car, with the opposite point towards the tail, and there fastened with a cord to another small bowsprit; this sail will be a protection, if large enough, in case of any accident occurring to the machine; it will then prevent the man from being precipitated to the ground in a manner similar to a parachute. I only have mentioned this sail that it may be resorted to if it be found necessary in a long voyage; the first experiment I would try without it.

A coachmaker is accustomed to make strong work with little weight of materials; he, therefore, would be the most proper person to make a machine of this kind. The man must sit in the middle, between the wings and the tail, so as to be a little behind the centre of gravity, for the purpose of causing a little preponderance of weight to act upon the back edge of the wings; for if there be not, in some degree, more weight behind than before, when the compressed air is making a resistance against the under-side and back edges of the wings, where it rushes upwards again, causing a great reaction, it would, of course, elevate the hinder part of the car too much.*

* This and the paragraph immediately preceding it are omitted in the second edition.—Eds.

The wings and the tail [passive surfaces] should be made of silk, very compactly woven, and [slightly done over with boiled linseed oil to make it] as impervious to the air as possible. The silk which the [active] wings are formed of should [perhaps] be laid on in separate broad slips,¹ and should open to admit the air to pass through as the wings move up, and close together again as they come down, in the same manner as I have described the action of the quill feathers in the wings of birds; although, upon the experiment being tried, this method may not be found so absolutely requisite, for we see flying squirrels, bats, butterflies, beetles, [and all other insects which fly, and] flying fish, etc., with wings formed of compact membranes, all flying exceedingly well. The Madagascar bat has a body the size of a rabbit, with wings four feet long, formed of entire membranes, and, although so large, it can fly as well as our little native bats; therefore it is possible that a pair of artificial wings may be formed without any valves [or slips], and yet answer equally well; but this can only be determined by actual trial.

It is necessary to observe that the car in which the man is to sit must be entirely covered on the outside [two sides] with silk or very thin leather, and along each side of the car the silk or leather must be *united* to the base of the wings, to prevent as much as possible the air from escaping anywhere but from the back edges of the wings; should that be neglected, when the air is compressed by

¹ The tail feathers of turkies laid close and parallel to each other and fast sewed upon eight pieces of strong riband, so as to form the same number of slips, then extended in the wing and well braced, would perhaps answer the purpose much better.—T.W. (This footnote is omitted in second edition.—EDS.)

the wings being struck downwards, it will rush upwards through the car and thereby fail of giving that resistance [*or diminish that reaction of the air*] against the underside [*and back edges*] of the wings which is necessary for the purpose of effecting buoyancy and progression.

I think that the *shafts* of the wings and tail would answer the purpose in the best manner, if they were each of them made of six long slips of thin whalebone, dressed tapering to a point, then wrapped together in a round form with small twine from end to end, and filled with cork along the inside.* By making them in this manner they would spring against the air, would be very light, and so strong that it would be impossible to break them with the power or weight of any one person. By forming them as above we shall humbly imitate the shaft of a quill feather, which is composed of a thin horny shell, containing a delicate light pith along the inside.

I here recommend my readers to *particularly observe* that a *main point in this treatise* is that they should not overlook the importance of the knowledge of the reaction of the air against the underside and *back edges of the wings*, for this is what causes the projectile motion, which is indisputably proved by the flying of my paper wings across a room, and which I will further illustrate by the flight of birds, mill sails, &c.

I have frequently conversed with persons about the art of flying by mechanical means, and generally found them disposed to treat the idea with ridicule. I have asked

* This was altered in the second edition to: "I think that the *shafts* of the wings would answer the purpose in the best manner, if they were each of them made of two long slips of thin whalebone, dressed tapering to a point, then wrapped together with small twine, and with pieces of cork along the inside, at the distance of about six inches from each other."—EDS.

them if they knew how birds were enabled to fly, and they mostly answered me nearly in the following manner : that birds could fly because it was natural to them, that they were covered with feathers, which were such light materials as to help them to fly, and that their wings are properly adapted for flying. This was as far as they could explain, which proved that *all* they knew on this subject amounted to nothing. They generally seemed to indulge an idea that there was something in the flight of birds either supernatural or incomprehensible ; but I hope my readers will be convinced, by this little treatise, that the art of flying is as truly *mechanical* as the art of rowing a boat.

[When I had convinced myself of having gained a *correct* knowledge of the cause of the projectile force of birds, I felt desirous of ascertaining how far it had been understood before ; I therefore examined our encyclopedias, and all other philosophical books any way likely to contain the information I sought for ; but nowhere could I find in print any light upon the subject ; I was then induced to publish the knowledge of those principles, with instructions for making a car in accordance with the principles of nature, for the purpose of travelling through the air. Subsequent to my treatise being published, there has been printed a supplementary volume to the Encyclopedia Londonensis, wherein an explanation of the cause of the projectile motion of birds is inserted.]

I will here further illustrate how flying is effected. The air, when struck upon by wings, produces an effect by its reaction against the underside and back edges, similar to that which is caused by the wind blowing with

sufficient force against a mill-sail, when it *rushes off on one side*, and impels the sail to move, with this difference only, that the sail, being fastened at one end to an axis, is made to revolve, whilst the bird, being at full liberty in the air, is caused, by the expansive power of the air acting with a resisting force *against the back edges* of the wings, to glide forward in a right line.

Most of my readers, I think, will acknowledge the great elastic power of the wind, as it is manifested by the sailing of ships and the revolving of mill-sails; these effects are produced by the wind being compressed against the sails from its own natural motion and force; but the effect the air has against the wings or sails of birds is produced by its being compressed, with them striking vertically upon it; and the larger they are made the greater quantity of air is compressed, by which means is caused a more powerful reaction, and consequently a more effectual buoyancy and progression. From this cause all the birds whose wings are *very large* in proportion to their weight are able to fly with the *least exertion* imaginable, whilst birds with very small wings are obliged to use very great labour indeed; this being demonstrated by the examination of the dimensions of birds' wings and their specific gravity, and by observing the different methods of flying.

I have often been delighted with the striking conviction that Supreme wisdom alone could have so nicely adjusted all the various internal and external organization of the vast number of different species of birds, to their diversified wants and modes of living; but it is only necessary to observe here that all those which are under the greatest necessity of flying are provided with the

longest and best proportion of wings and tails, and are consequently able to fly in the best manner, and those which need them less have them more limited, and are therefore less capable of flying, as if the all-wise Creator had set limits to their powers of flight, that they might not go out of their respective elements.

Although I think that a pair of wings seven or eight feet each in length would be sufficient, still, if I could make it convenient to try the experiment of flying, and were not prevented, as I am, by a chain of untoward and uncontrollable circumstances, I would cause the wings to be made of as large dimensions as I could possibly *move with ease*.*

I observe amongst the aquatic birds that the auks, guillemots, divers, etc., have such remarkably small narrow wings that they would be utterly incapable of keeping themselves up in the air if it were not for an exertion which they are obliged to make in the extreme. Their wings are moved with such rapidity as to be with difficulty discerned. In this we see the economy of the all-wise Creator, for according to their habits and appetites they have very little occasion to fly at any time, except during the time of incubation, when they have to ascend the most inaccessible rocks and cliffs they meet with along the sea shore, where they breed and rear their young; all the rest of their time they pass on or in the water, swimming and diving for their food.

All the gallinaceous class of birds have very short concave wings, which they strike with great exertion; they also, in general, have but little occasion to fly; their food, which consists principally of grain and seeds, being spon-

* This paragraph is omitted in the second edition.—EDS.

taneously scattered over the earth, they are almost constantly upon their legs, running about to pick it up, and seldom fly but to avoid danger.

On the other hand, rapacious birds, whose appetites induce them to be the greatest part of their time upon the wing, in search of a subsistence which is very precarious (as every inferior bird, &c., to which they direct their sanguinary attacks, from that love of existence which God has so strongly implanted in all His creatures, will use its utmost skill and activity to elude its destroyer), are much better accommodated, having wings of large dimensions they can repose upon the air, and project themselves forward with a gentle wafting. This is the class of birds I would copy from in the construction of a machine for artificial flying. The kite or glead, P, B, Z, (or *milvus* from Lin.,) is the best natural specimen that we can find in the British ornithology; this bird has very large flat wings, with a large forked tail, and flies with the least exertion, I believe, of any bird in the creation.

All the *hyrundo* class of birds are almost constantly flying; they all have bodies of little weight, have large *flat* wings, and fly with great ease. The goat-sucker, which is a species of nocturnal swallow, is admirably constructed for flying with facility.

As I have mentioned aquatic birds, I will here take the opportunity of execrating, with all the indignation of my soul, that savage and brutal amusement which they bring to my mind, and which so many persons frequently practise and take delight in; I mean the shooting these harmless and inoffensive birds [merely for sport]. Many are the parties who resort to Flamborough-head, for no other purpose than gratifying their vanity by making a display

of their dexterity in shooting, and causing all the havock they possibly can amongst the poor inoffensive birds. Barren must be their minds, and callous their feelings, who can take pleasure in destroying these innocent creatures, which are not in the smallest degree offensive to man when they are living, nor of the least service to him when killed. If these GENTLEMEN could eat them when they have done shooting, that would be some excuse ; but as their flesh is very rancid these wanton barbarians have no relish for their game. I wish their humanity was as nice as their appetites, they would not find delight in merely shooting them for sport and cruelty, leaving them, some killed and others wounded, floating on the surface of the sea, whilst their helpless young ones must consequently perish with hunger upon the shelvings of the rocks. Such amusements, surely, are not becoming rational beings, but may give pleasure to semi-rationals.

In the months of May and June these birds, which, during the rest of their time are dispersed over various parts of the ocean, are brought by one of the great impulses of nature to assemble at Flamborough-head in myriads, producing a throng, upon a great extent of cliff, similar to what we see in miniature in the front of a beehive, on a fine summer's day, when there is a perpetual egress and ingress of thousands.

A person who has never seen such a sight, and is capable of deriving pleasure from contemplating the economy and the works of nature, may find an exquisite gratification in paying a visit, at this season of the year, to Flamborough-head without having recourse to wanton acts of cruelty. Will there ever come upon the earth a genera-

tion of men who will despise all pleasures that are either unreasonable or inhuman?

Reason and *humanity* constitute the *only* permanent basis of all human happiness, and *real* honour and *true* glory of man! without which he is but a compound of folly and madness, and is too often a vile mischievous brute. By a disregard and contempt of these two divine guides families and nations become distracted and are made miserable, as we have too amply witnessed in the deplorable and wretched state in which Europe has been so long afflicted, where the appetite of the cannibal has *only* been wanting to complete the brutality of *civilized* nations. But I am departing too much from my original subject; I will withdraw my pen from this sickening view of poor, frail, erring, human nature!

After having described how to construct a machine to fly in, which, like the swift or great black martin (*apus*, Lin.), cannot fly from the surface of the ground, but must have an elevation to rise from, it becomes necessary that I should give directions how it may be made to ascend.* Set two tressels fast upon the ground, one six feet high and the other four and a half, at twelve feet distance

* The following directions were substituted in the second edition: "It becomes necessary that I should give directions how it may be launched upon the air, which may be done by various means; perhaps the following method may be found to answer as well as any: Fix a poll upright in the earth, about 20 feet in height, with two open collars to admit another poll to slide upwards through them, let there be a square platform made fast on the top of the sliding poll; place the car with a man in it upon the platform, then raise the platform to the height of about 30 feet by means of the sliding poll, let the sliding poll and platform suddenly fall down, the car will then be left upon the air, and by its pressing the air a projectile force will instantly propel the car forwards (fig. 9); the man in the car must then strike the active wings briskly upon the air, which will so increase the projectile force as to become superior to the force of gravitation; and if he inclines his weight a little *backward*, the projectile impulse will drive the car forward in an ascending direction (fig. 8). When the car is brought to a sufficient altitude," etc.—EDS.

from each other ; then lay upon them two or three planks, which will form a stage with an oblique plane, upon which the car must be placed, with its head pointing to the higher end of the stage.

A person may then get into the car, and sit a little behind the centre of gravity, which must be adjusted before the car is placed there ; being thus elevated he will have depth enough on each side of the car to admit of his wings striking upon the air. He must then push the lever forward about eighteen inches from its perpendicular line, the tips of the wings will then rise three feet and a half above the level of their joints ; he must then, with a brisk exertion, pull the lever backwards eighteen inches past the perpendicular line, and the tips of the wings will be struck downwards, passing through an arch of seven feet, and suddenly driving down and compressing the air in that arch, part of which will escape past the back edge of the wings (as I have described before), making at the same time a reaction which will push the wings forward : and as the car and the wings are first placed on an oblique plane, they will be impelled forwards, making an oblique ascent. The projectile impulse will naturally force the machine upwards in an angle in which the plane of the wings is laid, somewhat similar to what may be observed in the raising of a common paper kite, except in a right angle, or perpendicular line ; but the nearer the angle of ascent inclines to the line of the horizon, the easier will the machine be found to ascend. I believe pigeons can ascend very nearly in a perpendicular line, but such an ascent would be too incommodious for artificial flying.

When the car is brought to a sufficient altitude to clear

the tops of hills, trees, buildings, &c., the man, by sitting a little forward on his seat, will then bring the wings upon an horizontal plane, and by continuing the action of the wings he will be impelled forwards in that direction. To descend, he must desist from striking the wings, and hold them on a level with their joints; the car will then gradually come down, and when it is within five or six feet of the ground, the man must instantly strike the wings downwards, and *sit as far back* as he can; he will by this means check the projectile force, and cause the car to alight very gently with a retrograde motion. The car, when up in the air, may be made to turn to the right or the left [by forcing out one of the fins, having one about eighteen inches long placed vertically on each side of the car for that purpose,* or perhaps] merely by the man inclining the weight of his body to one side.

When I have seen a man sitting in a chair upon a tight rope, with a table before him, spread over with decanters, glasses, &c., &c., and, by his *dexterity alone*, be able to keep himself and all his accommodations exactly balanced there while he sat smoaking his pipe, apparently at perfect ease, I have been induced to consider the art of managing a flying machine, compared with such a surprising display of human dexterity, to be very simple; and see no reason why men should not become as expert in navigating the air as the sea.

As some of my readers, who may have little regard for anything but the *utile*, may be induced to ask, what use will flying be of, when it is attained? I beg leave, in the way of reply, to give the following hints:—I hope it will

* *Vide* Fig. 12.

be granted that flying will be of great use, if by such means we can have our letters, newspapers, &c., conveyed to any part of the kingdom at the rate of forty or fifty miles in an hour, or if that numerous class of mercantile agents who are now denominated riders, henceforth be enabled to glide through the air with great expedition, in flying machines; or if a man, by such means, can take a rope to any mariners in distress along the sea coast, and thereby become the happy instrument of saving their lives; and if the circumnavigator be able to quit his ship, fly and explore the interior parts of a new discovered island, free from the annoyance and hostilities of its rude inhabitants—but it would be tedious to enumerate all the uses to which artificial flying may be applied; it is obvious enough that when one man is enabled to fly, thousands may do the same, either on business or pleasure. It may tend greatly to reduce the vast number of horses kept in this kingdom, and by that means a very great quantity of land which is taken up at present in growing hay, oats, and beans for the support of these quadrupeds, might be then cultivated for the increase of our national stock of subsistence for the population; and I think it is evident that we have great occasion to reduce the superfluous number of those animals, and to employ all the land we possibly can to grow corn, &c., for our own subsistence. It is not improbable that some persons will ask if flying and all this can be accomplished, to which I answer that if my scheme for attaining the art be deemed a rational one, as I hope it will, I think we certainly ought to try the experiment.*

* This entire paragraph is omitted in the second edition.—EDS.

After the perusal of this work, I hope my readers will be fully convinced that all attempts which have been hitherto made in the art of flying have failed, not in consequence of the art being impracticable, but from the natural science of flying having never yet been fully understood. All that has ever been written and all the experiments that have ever been made towards attaining a knowledge of artificial flying by mechanical means display a chaos of unsettled thoughts very wide and deficient of the principles of nature ; but I hope it will be granted that I have clearly discovered and demonstrated the whole of those principles upon which flying depends, particularly the *cause* of the *projectile motion* of birds. This is a discovery of the greatest importance, for as the air is continually acting, in the manner I have described, against the back edges of the wings, and thereby impelling the bird forwards with great force, *it positively has as much tendency to overcome specific gravity as the expansion of the wings has*. This is a fact demonstrated very clearly by my paper wings and by the manner of flying peculiar to some birds, particularly the woodpeckers. When one of these extraordinary birds has struck its wings once or twice upon the air, and thereby produced a projectile impulse sufficient to force it forward to a considerable distance, it instantly contracts its wings *as close to its sides* as when perched on a bough, and continues flying several yards with its wings kept *close* in that position until the impulse is abating ; it then throws out its wings again, gives another stroke or two to renew the impulse, *shuts them up*, and is again driven forward ; thus continuing to fly by distinct and separate projectile impulses alone. Here then we see the great importance of a true

knowledge of the cause of the projectile motion of birds, for this surprising bird does not depend upon a continued expansion of wings to keep itself up in the air, but is kept up and carried forward by the projectile force alone !

The green woodpecker is about the size of a pigeon, and, as it is very common in every part of England where wood abounds, many of my readers may have an opportunity of observing its curious method of flying ; the same may be observed of the beautiful little goldfinch, and of linnets. Here the physico-theologist, who is accustomed to contemplate the wisdom of God in all His works, might be led to infer that He has caused this deviation from the general method of flying, in order to demonstrate to us the *effect* of the projectile *force*, and that it is one of the *greatest essentials* in the art of flying, and perfectly distinct from and independent of the continued expansion of wings.

When we see pigeons flying *upwards* in the angle of *sixty* or *seventy*, as we do every day, from the streets to the tops of houses, with the plane of their wings parallel to the line of their ascent, I think they prove in a satisfactory manner the great effect of the *projectile force* [against the back edge of the wings] ; for without we admit this to be the cause of their ascending in such angles, how can we possibly account for it in any other way, upon rational principles ? *Vide* Fig. 10.

A stone thrown by the hand, and a ball ejected from the mouth of a cannon, are made to overcome specific gravity, and fly to a great distance ; we all know that these are not kept up by wings, but entirely by the projectile force. In fact, it is by the air being made con-

tinually to push the bird forwards [by a projectile force, exceeding the force of gravity], which constitutes the main cause of flying.

We must attribute to a total ignorance of the fundamental principles, that the art of flying has not been brought hitherto into common practice; for an art, so practicable as it is, must at any period of time have soon succeeded a discovery, such as I have made; and now that the art appears so very attainable, I hope that every friend to arts and sciences will acknowledge that it ought to have a fair trial.

I shall now conclude my treatise on flying with an appeal to the candour and good sense of my readers, whether the arguments I have used, and the principles upon which I have insisted the art of flying may be accomplished, are not such as give it a just claim to their approbation; for I think I may affirm, without being

accused of arrogance, that the art of flying has never before been treated of upon such rational and scientific principles.¹

[I will offer an additional plan for ensuring success in navigating the air. Should it be found necessary, after giving the above plan a full and fair trial, to have an auxiliary power, the silk of the two extended passive wings may be put together *double*, and then inflated with hydrogen gas; this would increase the sustaining power but I firmly believe this will not be required.]

Having now submitted to the good sense of my countrymen the whole of what I intended on the subject of

¹I will here take the liberty of communicating a few hints, which I conceive to be of importance to the aerostatic science. Now that we know the true cause of the projectile motion of birds, and I having suggested a plan for producing the same effect by artificial means, we may be able to accomplish what Messrs. Roberts, Blanchard, and others attempted to do, but in vain, entirely from their not possessing a knowledge of this mystery of nature. I am alluding to the steerage of balloons, which they endeavoured, with great labour, to attain, by striking a number of oars *horizontally* against the air; and if we do but take into consideration that the balloon was constantly flying from the air against which they were striking, it does not seem probable that they could, by such means, produce the effect they aimed at.

But if we make a car from the plan which I have laid down in this treatise, and upon a scale large enough to admit of one of Messrs. Mead and Co.'s new invented revolving steam engines, to move the lever with, we then can work, in a *vertical direction*, a pair of *very large wings*, which would produce a *projectile force* sufficient to impel the balloon forward in any point of the compass to which we might incline it; and by having a large tail fixed to the car, in an universal joint, we should be able to give it any inclination whatever; and when we have thus effected a perfect steerage to balloons, we shall be able to convey a number of passengers to any place of destination with accuracy and safety. But for this kind of navigation the balloon must be much smaller than usual, and perfectly spherical, and the gas should be kept in such a degree as not to have too great a tendency to ascend—it should be so regulated as to float in equilibrium with the atmosphere; the aeronauts could then keep the machine at a moderate height—from fifty to a hundred feet would be high enough for ordinary sailing, and if it was found to be inclining too much upwards, it might be counteracted by holding the tail in a descending direction. One of Mr. Mead's patent steam engines can be made with a one-horse power, or equal to the strength of eight or ten men, *that will not weigh more than eight stone*; and will stand in the small space of four feet by two, with the boiler and all the apparatus belonging to it.—T.W. (This foot note was omitted in the second edition.—EDS.)

flying, I, for the present, most respectfully take my leave of them, indulging a hope that the prediction of Bishop Wilkins, expressed in a former page, will soon be verified, and trusting that I shall not be disappointed in the opinion I entertain respecting the patronage which they will extend towards the invention now laid before them. [As we have mining companies, steam-packet companies, canal companies, railway and steam-coach companies, gas-light companies, &c., &c., we shall not, *I hope*, be long without a company for establishing the art of flying by mechanical means.] Encouraged by the public, I shall not abandon my purpose of making still further exertions to advance and complete an art, the discovery of the *true principles* of which, I trust, I can with verity affirm to be exclusively my own.

THE
AERONAUTICAL SOCIETY OF GREAT BRITAIN

Assistant Secretary and Librarian :

T. O'B. HUBBARD, 53, VICTORIA STREET, WESTMINSTER, S.W.

I.—OBJECTS OF THE SOCIETY

The Society (established 1866) was the first ever formed in any country, and is now in the 45th year of its existence. Its objects are:—

- (a) To give a stronger impulse to the scientific study of aerial navigation in all its branches.
- (b) To promote the intercourse of those interested in the subject at home and abroad.
- (c) To aid, with advice and instruction, those studying the principles upon which Aeronautical Science is based.

From its foundation, the Society has made a special study of dynamic flight, giving it the priority over ballooning.

II.—THE WORK OF THE SOCIETY

In order to carry out the objects for which the Society exists, the following arrangements are made:—

- (a) **Meetings of the Members** are held at which papers on aeronautical subjects are read and discussed.

These meetings are usually held quarterly, and have, except for a short period, been carried on ever since the Society was first established. The papers are read by Members and other persons interested in aeronautical science, and the discussions which follow them are often of great interest. All Members can attend these meetings and introduce two visitors.

Minor Meetings of an informal nature are also held monthly at the Society's Offices.

- (b) **A Quarterly Journal** is published and issued to members free of charge. The original "Reports of the Aeronautical Society of Great Britain" (23 in number) were issued annually, and are of considerable value, as they contain a great deal of useful information on aeronautical subjects, and may almost be said to form the basis of modern aeronautical science.

In 1897 the *Aeronautical Journal* was substituted for the Reports (the issue of which had lapsed), as it was considered that a quarterly issue would more effectually carry out the objects for which the Society exists. This Journal contains full reports of the Society's meetings, and is well illustrated. A great deal of miscellaneous aeronautical information is also given in it, a special feature being reviews of current aeronautical literature.

- (c) **A Library** is maintained. This library contains nearly all the well-known aeronautical works, some of them being of great value, and all modern books and publications can be borrowed by members. It is well supplied with the journals, magazines, etc., of other societies and clubs, both at home and abroad, and is a very beneficial institution to those who desire to gain a true knowledge of aeronautical science.

Books, lantern slides, and models for lecture purposes are issued on loan to Members only.

- (d) **Advice and Information** on aeronautical subjects. Members requiring information on particular points are placed in communication with other Members specially qualified to give the required information. A great deal of general information is available to Members on enquiry at the Society's Offices.

Members travelling abroad are furnished with introductions to foreign aeronautical societies, and are thus brought in touch with foreign aeronautical lines of development.

It may be mentioned here that the Society is well represented on the only two international scientific societies, viz., "The International Commission for Scientific Aeronautics" and "The Permanent International Aeronautical Committee."

- (e) **An Experimental Ground** is provided. During 1909, this was at Dagenham, Essex. New arrangements are now being made and will be communicated to Members in due course.
- (f) **An Experimental Laboratory** is in process of formation, from which it is hoped to obtain exceedingly valuable data.
- (g) **Medals** are awarded by the Society for distinguished services to aeronautics, particularly for scientific research and experiment.
A Bronze Medal is also awarded annually to the author of the best paper appearing in the *Aëronautical Journal* during the year.

GOLD MEDALLISTS.—Wilbur and Orville Wright (1909).

SILVER MEDALLIST.—Samuel F. Cody (1909).

BRONZE MEDALLISTS.—W. R. Turnbull (1908),

F. W. Lanchester (1909).

- (h) **Reports** by the Committees are published periodically. Reprints of valuable contributions to the science are occasionally issued. The following have already appeared:—

1897. "The Navigation of the Air," by Alex. McCallum. (Reprinted from the *Glasgow Herald*.)

1910. "Aeronautical Classics." 6 vols. (including the writings of Sir George Cayley, F. H. Wenham, T. Walker, F. J. Stringfellow, P. S. Pilcher, etc., which are being published at intervals during the year).

III.—SUBSCRIPTIONS, ETC.

1. The Entrance Fee is £1 ls., which should be forwarded with the application for membership, and is returnable in the event of non-election.

2. The Annual Subscription to the Society is £1 ls., payable on January 1st each year. Members joining after October 1st in any year do not pay subscriptions for the following year.

3. The annual subscription (optional) to the Experimental Ground Section is £1 la.

Members *who subscribe* to this section are allowed to make use of the ground at any time, and can always introduce one visitor.

Members *who do not join* the experimental ground can only use the ground for flying models not exceeding 20 lbs. in weight, on Saturdays, and on certain other special days (notified beforehand). They cannot introduce visitors, but can visit the ground as spectators at any time.

IV.—MEMBERSHIP

Members' names come up for election at the first Council Meeting held after the receipt of their membership application forms.

Anyone desirous of becoming a member should apply to the Secretary, from whom all particulars may be obtained.

V.—PRESIDENTS OF THE AÉRONAUTICAL SOCIETY OF GREAT BRITAIN

1866-1896. HIS GRACE THE DUKE OF ARGYLL.

1896-1901. [No President appointed.]

1901-1907. MAJOR B. BADEN-POWELL (*Scots Guards*).

1907. E. P. FROST, D.L. J.P.
